#### Abstract

Oxidation of H3 at lysine 4 (H3K4ox) by lysyl oxidase-like 2 (LOXL2) generates an H3 modification with an unknown physiological function. We find that LOXL2 and H3K4ox are higher in triple-negative breast cancer (TNBC) cell lines and patient-derived xenografts (PDXs) than those from other breast cancer subtypes. ChIP-seq revealed that H3K4ox is located primarily in heterochromatin, where it is involved in chromatin compaction. Knocking down LOXL2 reduces H3K4ox levels and causes chromatin decompaction, resulting in a sustained activation of the DNA damage response (DDR) and increased susceptibility to anticancer agents. This critical role that LOXL2 and oxidized H3 play in chromatin compaction and DDR suggests that functionally targeting LOXL2 could be a way to sensitize TNBC cells to conventional therapy.

[^0]
## Introduction

Histone modifications contribute to gene regulation both by directly affecting chromatin structure and by recruiting effector proteins [1]. Deregulation of this enzymatic system can contribute to diseases, including cancer. The lysyl oxidase family of proteins are copper- and quinonedependent amine oxidases that oxidize the amino group located in the epsilon-position in lysines, thereby generating an aldehyde group [2]. One of the members of the LOX family, lysyl oxidase-like 2 (LOXL2), deaminates unmethylated and trimethylated lysine 4 in histone H3 (H3K4me3) through an amino-oxidase reaction that uses the $\mathrm{Cu}(\mathrm{II})$ ion and the internal cofactor lysine-tyrosylquinone, releasing the amino group and converting K4 into an allysine (H3K4ox) [3, 4]. Generation of this peptidyl aldehyde likely alters the local macromolecular structure of chromatin and the nature of any protein-protein or protein-nucleic acid interactions. This is particularly relevant for gene regulation, as changes in the macromolecular status of histones can affect chromatin conformation [4-6].

LOXL 2 is overexpressed in many tumors, and especially in breast cancers [7-9]. In this light, it is intriguing that some breast cancers are intrinsically resistant to chemotherapy; for these subtypes, chemotherapy induces a mesenchymal phenotype through the epithelial-to-mesenchymal transition
(EMT) [10]. EMT is likely to be a critical switch for tumor cell invasiveness and cell death resistance [11-13] and to involve chromatin reorganization, as it requires dramatic changes in cellular characteristics and gene expression [6, 14]. Notably, the key transcription factor Snail1 interacts with LOXL2 [15], and LOXL2 H3K4 oxidase activity generates an H3K4ox that regulates the repression of the Ecadherin gene ( CDH 1 ) and heterochromatin transcription, which play roles in two essential steps of EMT [6, 16].

Double-strand breaks (DSBs) are a major form of DNA damage and cause a specific signaling response, the DNA damage response (DDR), which can activate cell cycle checkpoint arrest and cell fate decisions, such as apoptosis or senescence. One of the first steps of DDR is the accumulation of DNA repair proteins at the damaged site [17]. Importantly, DDR activation can occur in the absence of DNA damage, by stable association of the repair factors with chromatin [18, 19]. Moreover, increasing evidence suggests that higher-order chromatin structures affect DSB repair and signaling [20]. For example, DDR actively regulates decondensation of chromatin after DSBs [21], and it is amplified when chromatin is in an "open" state [20]. Similarly, DDR signaling is affected by chromatin compaction in a DNA damage-independent manner [18, 19, 22-24].

We addressed the physiological functions of H3K4ox using an in-house generated antibody specific for this modification to analyze the H3K4ox levels in distinct breast cancer subtypes. Intriguingly, mesenchymal triple-negative breast cancer (TNBC) cell lines as well as breast cancer patient-derived xenografts (PDXs) had high H3K4ox levels that correlated with high LOXL2 expression, as compared with other subtypes. Using ChIP-seq to map its genome-wide localization, we found that H3K4ox was enriched in heterochromatin in TNBC cells, which are highly metastatic and resistant to chemotherapy. Decreasing LOXL2 levels reduced the amount of H3K4ox in chromatin, resulting in chromatin decondensation and a sustained activation of DDR. Further, both LOXL2 depletion and treatment of TNBC with chromatin-modifying drugs sensitized cancer cells to conventional treatments. Thus, targeting H3K4ox levels may open a new therapeutic window for this subtype of breast cancer.

## Results

## Generating an H3K4ox-specific antibody

We initially generated a specific antibody for the recently discovered histone modification of H3K4ox, as a prerequisite for studying its physiological function. As the aldehyde group generated by LOXL2 reaction on
trimethylated lysine 4 is highly reactive, and hence unfit for immunochemical studies, we hypothesized that a primary alcohol might provide a similar oxygen-bearing functionality that is less reactive, in order to generate a modificationspecific antibody that provides a readout of H3K4ox (Fig. 1a). We therefore synthesized a H3 peptide containing a 6-hydroxynorleucine residue as allysine at position 4 and used this for rabbit immunization (Fig. 1b). The resulting H3K4ox antibody was highly specific for the H3K4ox peptide, with very low cross-reactivity for unmodified H3 and no detected cross-reactivity for H3K9me3 or H3K4me3, in a wide range of experimental conditions (dot blots, western blots, and chromatin immunoprecipitation (ChIP) experiments) (Fig. 1c-f). Analysis of purified nucleosomes from 293T cells showed that H3K4ox levels increased, and H3K4me3 levels decreased, when nucleosomes were incubated with wild-type (wt) recombinant LOXL2 but not with a catalytically inactive LOXL2 (LOXL2mut) [3] (Fig. 1d, upper panel). Moreover, the levels of H3K4ox also increased in MCF-7 cells transfected with LOXL2 as compared with cells transfected with the empty vector (Fig. 1d, lower panel). Finally, MDA-MB-231 cells infected with an shRNA targeting the human LOXL2 (LOXL2 knockdown (KD)) showed a specific reduction in H3K4ox levels as compared with cells infected with an irrelevant shRNA (control), in both western blots and ChIP-PCR experiments using the E-cadherin gene promoter ( CDH 1 ), which is a well-known LOXL2-mediated H3K4 oxidation target promoter (Fig. 1e) [3, 4]. Kinetics of the reaction using recombinant LOXL2 and nucleosomes revealed that levels of intermediate alcohol were maintained for 2 h , after which they were reduced (Fig. 1f). Biotinylated hydrazide was used to detect the generated aldehyde group, which appears after 4 h of reaction (Fig. 1f). Thus, as the intermediate alcohol is relatively stable, the antibody we generated can be used as a readout of the oxidized histone H3K4, although we cannot distinguish whether it recognizes the intermediate alcohol, the aldehyde group, or both.

## H3K40x maps to heterochromatin and controls chromatin accessibility in TNBC cells

As aberrant expression and activity of LOXL2 have been reported in various cancer types [7-9], we checked the levels of LOXL2 and H3K4ox in several breast cancer cell lines representing different subtypes: luminal A , in the T-47D and MCF-7 cell lines ( $\mathrm{ER}^{+} / \mathrm{HER} 2^{-} / \mathrm{PR}^{+/-}$); luminal B , in the BT474 cell line $\left(\mathrm{ER}^{+} / \mathrm{HER} 2^{+} / \mathrm{PR}^{+/-}\right)$; and basal TNBC, in the human MDA-MB-231 (ER ${ }^{-} / \mathrm{HER}^{-} / \mathrm{PR}^{-}$) cell line [25]. As compared with the other cell lines, MDA-MB-231 (TNBC) showed high levels of LOXL2 and a corresponding

The red circle indicates the intermediate residue that is targeted by the in-house generated antiH3K4ox antibody. b The artificial amino acid 6-hydroxynorleucine was used in the peptide to generate the anti-H3K4ox antibody. c The anti-H3K4ox antibody was found to be specific in western blot in two replicates of dot blots of dilution series of oxidized histone H 3 peptide (H3K4ox) or unmodified H3 peptide (left panel), as well as in a representative dot blot of a dilution series of H3K9me3, H3K4ox, H3K4me3, or H3 peptides (right panel). d Nucleosomes were incubated with recombinant wild-type (wt) LOXL2 or a catalytically inactive LOXL2 (mut) purified from baculovirus to detect H3K4ox/ H3K4me3 levels (upper panel). Lysates of MCF-7 cells transfected
enrichment of H3K4ox (Fig. 2a). Levels of H3K4ox also paralleled increases in LOXL2 expression levels in other TNBC cell lines (e.g., MDA-MB-468, CAL-51, HS-578-T, and BT-549), although with variable LOXL2 expression levels (Fig. 2b). Finally, comparing PDXs from luminal (3 PDXs) or TNBC (6 PDXs) subtypes of breast cancer, we
with an empty vector ( $\varnothing$ ) or with LOXL2 were analyzed by western blotting, using the indicated antibodies (lower panel). e Western blot for LOXL2, H3K4ox, and total H3 from MDA-MB-231 cells infected with short hairpin RNA (shRNA) as a control, or a knockdown (KD) using a shRNA specific for LOXL2 (LOXL2 KD) (left panel). AntiH3K4ox ChIP-PCR was used to analyze the E-cadherin gene (CDH1) promoter in MDA-MB-231 cells infected with shRNA for either control (green bar) or LOXL2 KD (blue bar). Data of qPCR amplifications were normalized to the input and to total H 3 for each condition. Error bars indicate the SD from at least three independent experiments. $* * P<0.01$. f Western blot of H3K4ox and biotin incorporation (BTH-H3) in nucleosomes incubated with recombinant LOXL2 purified from baculovirus, after different incubation times
found that in all TNBC PDXs the levels of H3K4ox were higher compared with luminal PDXs. In addition, in four out of six TNBC PDXs H3K4ox levels also correlated with high LOXL2 expression. (Fig. 2c).

To elucidate the function of H 3 K 40 ox in breast cancer cells, we first performed a ChIP-seq experiment with the
anti-H3K4ox antibody to determine the genomic distribution of H3K4ox in the MDA-MB-231 cells. Peaks called using model-based analysis for ChIP-seq (MACS) [26] showed low differences in H3K4ox between two sequencing replicates, with a genome-wide Pearson correlation coefficient of the read count of the two replicates of 0.997 (Fig. 2d, upper panel). We observed that H3K4ox peaks were distributed throughout different genomic elements (Fig. 2d, lower panel). Using the ChromHMM tool [27], we assessed the statistical overrepresentation of the H3K4ox peaks through different chromatin states (promoter, weak or strong enhancer, insulator, repressed, or heterochromatin [nonrepetitive sequences]) and found that H3K4ox peaks were significantly overrepresented in heterochromatin (Fig. 2e, f). As generating an aldehyde in H 3 removes a positive charge and creates a very reactive group, we hypothesized that this reaction affects chromatin structure. To test this, we used the assay for transposase-accessible chromatin [28, 29] followed by deep sequencing (ATAC-seq), which exploits the ability of the prokaryotic transposase $\operatorname{Tn5}$ to integrate preferentially into accessible (open) chromatin. ATAC-seq showed an increased ATAC signal in LOXL2 KD cells, but not with control cells, at H3K4ox-positive sites (Fig. 2g). These results were validated in selected regions by ChIPqPCR and ATAC-qPCR in control and LOXL2 KD cells: H3K4ox enrichment decreased in LOXL2 KD cells, with a correlating increase of ATAC signal, in these regions (Fig. 2h). No changes were observed in a control promoter, POL2RA (Fig. 2h). These data demonstrated that, in the absence of LOXL2, H3K4ox levels decrease and chromatin adopts a more open conformation (Fig. 2g). Thus, our results showed that H 3 K 4 ox is enriched in heterochromatin and is directly linked with chromatin accessibility in those regions.

## Chromatin structure alterations activate DDR in a LOXL2-dependent manner

As the chromatin state can influence many aspects of DDR [30], we hypothesized that disruption of LOXL2 expression and impairment of H3K4ox generation might influence DDR by affecting chromatin accessibility. To test this, we analyzed by immunofluorescence MDA-MB-231 cells that had been infected with either LOXL2 KD or control lentiviruses, using two well-established markers of DDR: phosphorylated $\mathrm{H} 2 \mathrm{AX}(\gamma-\mathrm{H} 2 \mathrm{AX})$ and TP53-binding protein 1 (53BP1). Depletion of LOXL2 (using LOXL2 KD) led to more foci of both $\gamma-\mathrm{H} 2 \mathrm{AX}$ and 53BP1 than in control cells, suggesting that LOXL2 KD cells may accumulate DNA breaks and/or activate DDR (Fig. 3a). To determine if the LOXL2 catalytic activity was involved in the observed
phenotype, LOXL2 KD cells were complemented by reinfection with ectopic vector expressing either the wt LOXL2-IRES-GFP or a catalytically inactive LOXL2 (LOXL2mut-IRES-GFP), both of which were expressed at similar levels (Fig. S1). Fewer $\gamma$-H2AX and 53BP1 foci were observed in LOXL2 KD cells after reintroduction of the wt (but not of the catalytically inactive) LOXL2 (Fig. 3b), establishing that suppressing DDR activation requires both the activity of LOXL2 and H3K4ox generation.

## LOXL2 KD activates DDR independently of DNA damage

Increased DDR activation in LOXL2-depleted cells could be a consequence of more DSBs due to reduced H3K4ox levels and/or chromatin decondensation. Notably, aberrant silencing and conflicts between replication forks and transcription, as well as the presence of R-loops (a transcriptional intermediate), can result in DNA damage and are influenced by chromatin state, for example in cells lacking the linker histone H1 [31]. However, our analysis of RNAseq data revealed that LOXL2 KD cells did not have altered expression of repetitive elements (Table 1), and DDR activation in LOXL2 KD cells was not affected by cordycepin, an inhibitor of RNA synthesis that abolishes R-loop formation [32, 33] (Fig. 3c). As R-loops can generate DNA damage during replication due to fork stalling and collapse [32, 34], we next analyzed $\gamma$-H2AX and 53BP1 foci in noncycling LOXL2 KD cells and found DDR activation to also be increased (Fig. 3d). Overall, these data suggested that overexpression of repetitive elements, R-loop formation, and replication fork stalling were not responsible for activating DDR following LOXL2 depletion, when heterochromatin adopts a more open state. As chromatin structure alterations can trigger the DDR, even in the absence of DNA damage [22, 35, 36], we checked for the presence of DNA damage following LOXL2 depletion more directly, using the comet assay, in LOXL2 KD or control cells under alkaline conditions. No increases in DNA damage (due to either single-strand or double-strand DNA breaks) were observed in LOXL2 KD cells (Fig. 3e). Moreover, we did not observe any significant differences in chromosomal lesions between LOXL2 KD or control cells in metaphase spreads (Fig. 3f). Finally, analyzing for mitotic aberrations (anaphase bridges and micronuclei), which can be indicative of replication stress or DNA repair defects, we observed only a mild increase in anaphase bridges in the absence of LOXL2 (Fig. S2). Taken together, our data suggested that the combination of loss of LOXL2 and reduced H3K4ox levels in TNBC cells was sufficient to activate the DDR in the absence of detectable DNA lesions.

## Alterations in chromatin compaction activate the DDR

To further address the origin of DDR signaling in LOXL2depleted cells, we analyzed the behavior of additional DDR signaling components. As both $\gamma$-H2AX and 53BP1 foci formation require the ATM kinase in some settings, we
treated LOXL2 KD and control cells with the ATM inhibitor KU55933 and analyzed foci formation (Fig. 4a). Decreased foci of both markers were observed upon ATM inhibition, indicating that LOXL2-induced DDR was largely ATMdependent. Consistent with this, LOXL2 KD cells had increased phosphorylation of several ATM substrates, including KAP-1, CHK1, and CHK2 (Fig. 4b). However,

4 Fig. 2 H3K4ox maps to heterochromatin and controls chromatin accessibility in TNBC cells. Data of qPCR amplification were normalized to the input and to total H3 (upper panel). ATAC-qPCR validation of the incorporation of the transposase Tn5 at the selected genomic regions from the ChIP-seq from control or LOXL2 KD MDA-MB-231 cells. Data of qPCR amplification were normalized to an unchanging genomic region (the $H P R T$ promoter) and expressed as the fold-change relative to data obtained from control cells, which were set to 1 (lower panel). In both experiments, the RNA polymerase II ( $P O L 2 R A$ ) promoter was used as a negative control. Error bars indicate the SD from at least three independent experiments. $* P<0.05, * * P<0.01, * * * P<0.001$
we ruled out that increased DDR signaling was due to apoptosis in LOXL2 KD cells, as no cleaved caspase-3 signal was observed in either LOXL2 KD or control cells (Fig. S3a). As these data suggested that the LOXL2 KD cells activated a checkpoint response, we analyzed cell cycle progression following LOXL2 depletion. After synchronization with a double thymidine block, LOXL2 KD cells were not able to efficiently progress through the cell cycle (Fig. 4c), and western blotting for H3S10-P showed that this histone mark was undetectable in LOXL2 KD cells as compared with control cells. (Fig. 4d). These data strongly suggested that LOXL2 KD cells arrested primarily in G1. Consistent with this possibility, cell proliferation capacity of LOXL2 KD cells was blocked (Fig. 4e, upper panel), and their colony-formation capacity was strongly reduced after only a few passages (Fig. 4e, lower panel). This effect on proliferation was further confirm by gene ontology analysis of the gene expression pattern of LOXL2 KD cells (Fig. S3b; Tables 2 and 3).

To test whether the effects on chromatin in LOXL2 KD cells directly activated ATM-dependent DDR signaling, we forced chromatin condensation in these cells by expressing the linker histone H1 or the H3K9 methyltransferase SUV39 H 1 (as green fluorescent protein (GFP)-labeled proteins) and counted the number of $\gamma$-H2AX foci in GFP-positive cells. Notably, overexpression of either $\mathrm{H}^{\text {GFP }}$ or SUV$39^{\mathrm{GFP}}$ in LOXL2 KD cells reduced the number of $\gamma-\mathrm{H} 2 \mathrm{AX}$ foci as compared with LOXL2 KD cells that expressed GFP alone ( $+\mathrm{MOCK}^{\text {GFP }}$ ) (Fig. 4f, g). This suggested that lack of LOXL2 and reduced H3K4ox levels affected the regulation of chromatin condensation (leading to decondensation) and activated DDR, even in the absence of DNA damage.

## LOXL2 reduction enhances chemosensitivity of TNBC cells

We found that reducing H3K4ox levels via LOXL2 depletion led to chromatin decondensation, triggered DDR activation, and induced cell cycle arrest, suggesting that LOXL2 inhibition could be interesting as a breast cancer treatment. As no LOXL2-specific inhibitors are currently available, we therefore tested whether reducing the levels of functional LOXL2 would increase the sensitivity of breast cancer cells to chemotherapy. For this, we treated three different TNBC cell lines with doxorubicin (a topoisomerase inhibitor that generates DSBs) either alone or together with trichostatin A (TSA) (a general HDCA inhibitor [37] that increases chromatin accessibility [38]). Indeed, we observed that in all cases, treatment of doxorubicin together with TSA increased the percentage of cell death-indicative of an increased cell sensitivity to chemotherapy (Fig. 5a). Similar results were obtained with two TNBC_PDXs (PDX549 and PDX-154) (Fig. 5a). To determine if these results were reproducible in vivo, PDX-549 cells were first grown ex vivo, and then $10^{6}$ cells were subcutaneously implanted in nude mice. After tumor formation, mice were treated with TSA, doxorubicin, doxorubicin plus TSA, or (as a control) vehicle for 25 days. In agreement with our previous results, we observed that tumor growth was substantially impaired with the combined TSA/doxorubicin treatment (Fig. 5b).

## Discussion

In this work, we found that several TNBC cell lines and PDXs express high levels of LOXL2 as compared with those of the luminal breast cancer subtype. With the use of a newly generated antibody, we were able to detect the H3K4ox modification produced by LOXL2 [3] and we observed how this histone H3 modification was higher in all TNBC cell lines and PDXs as compared with luminal subtypes. This H3 modification is enriched in heterochromatin and is required to maintain the condensed heterochromatin state. It is possible that during tumor progression, some cancer cells undergo the EMT program and start to express LOXL2. The transcription factor Snail1, together with LOXL2, would participate in downregulating the CDH 1 gene and other heterochromatin transcripts, giving rise to transformation of cancer epithelial cells into mesenchymal cells (through EMT) [6, 39-41]. Recently, two different groups have suggested that EMT is dispensable for lung and pancreas metastasis but contributes significantly to the formation of recurrent metastasis after chemotherapy [42, 43]. This finding is in agreement with our results, in which we observed that the most aggressive and resistant subtype of breast cancer (TNBC) has a

4 Fig. 3 Chromatin opening activates DDR via a mechanism that requires catalytically functional LOXL2 but can be independent of DNA damage. a $\gamma$-H2AX and 53BP1 staining and foci quantification are shown by immunofluorescence with a specific antibody for $\gamma$-H2AX (left image) or for 53BP1 (right image). mesenchymal phenotype and is enriched for H3K4ox in its heterochromatin. We observed that reducing H3K4ox levels perturbed the balance between condensed and decondensed chromatin and activated the DDR. Similar phenotypes have been previously observed after depletion of SUV-39, PRDM2, or HP1, which are required for heterochromatin maintenance and cell survival after DNA damage [23, 24, 44, 45]. H3K4ox levels have been correlated to the repression of $\mathrm{CDH1}$ and major satellites (heterochromatin transcripts) during the EMT program [3, 4, 6]. $\mathrm{CDH1}$ is upregulated in TNBC cells when LOXL2 is knocked down and the levels of H3K4ox are decreased; however, the H3K4ox modification does not seem to be involved in repression of heterochromatin transcripts, as we did not observe increased levels of heterochromatin transcripts in LOXL2 KD conditions. Notably, downregulation of heterochromatin transcripts during EMT occur at a specific timepoint during chromatin reorganization, after which the levels of transcription recovered despite the presence of H3K4ox. Intriguingly, although upstream DDR signaling is sustained when chromatin is maintained in a condensed state [22, 46, 47], we found that forcing chromatin decondensation was sufficient to activate DDR signaling in the absence of any detectable DNA lesions. It seems that an abnormal, unbalanced ratio between condensation and decondensation leads to persistent DDR signaling. As LOXL2 has multiple substrates besides histones [5], we cannot discard an additional putative role for LOXL2 in the
direct regulation of the DDR machinery. However, we observed that the DDR induced in the absence of LOXL2 can be inhibited by forcing chromatin to condense using either of two different approaches, suggesting that the main molecular mechanism is the regulation per se of the chromatin compaction state.

While a correlation between chromatin compaction and DDR has been previously reported [22, 46, 47], we demonstrated here that H3 oxidation by LOXL2 is another molecular mechanism that maintains compaction. Notably, LOXL2 has been widely linked to cancer and the acquisition of cellular malignancy, as it is overexpressed in many tumors [15, 48-51] and has an important role in tumor formation [52].

Induction of chromatin compaction has been suggested as a potential therapeutic tool in gliomas, in which chromatin compaction limits DDR [46] and promotes damage resistance [53]. However, this does not appear to apply to TNBC cells. In support of this, we have now shown that several TNBC PDX tumors treated with TSA, a histone deacetylase inhibitor that generates an open chromatin state, enhanced tumor killing with doxorubicin in these cells. These observations suggest a rationale for studying combinations of "chromatin opening drugs," including inhibitors of histones deacetylases, EZH2, or LSD1, as a strategy for overcoming resistance to treatment in TNBC.

## Materials and methods

## Cell lines, transfections, and infections

Most of the cell lines used in this work (the TNBC lines MDA-MB-468 (ATCC HTB-132), CAL-51 (CSC-C0382), HS-578T (ATCC HTB-126), and MDA-MB-231 (ATCC HTB-26), the luminal A T-47D (ATCC HTB-133), MCF-7 (ATCC HTB-22D), and luminal B BT-474 (ATCC HTB20)) as well as cells isolated from PDXs, were maintained in Dulbecco's modified Eagle's medium (Biowest; L0106500); the TNBC line BT-549 (ATCC HTB 122) was maintained in Roswell Park Memorial Institute medium (Biowest; L0501-500). All cell cultures were supplemented with $10 \%$ fetal bovine serum (Gibco; 10270106), 2 mM Lglutamine (Biowest; $\mathrm{X} 0550-100$ ), and $1 \%$ penicillinstreptomycin (Gibco; 15140122) at $37{ }^{\circ} \mathrm{C}$ in $5 \% \mathrm{CO}_{2}$. All cell lines were regularly tested for the absence of mycoplasma using standard polymerase chain reaction (PCR). For LOXL2-Flag overexpression assays, MCF-7 cells were seeded for 24 h and transfected with $10 \mu \mathrm{~g}$ pcDNA3-hLOXL2-Flag vector using polyethylenimine polymer (Polysciences Inc; 23966-1). Lentiviral particles were produced in HEK293T cells (ATCC CRL-3216) for lentiviral infections to produce $L O X L 2$ KD cells. Cells were grown to

$70 \%$ confluency and then transfected by dropwise addition of $\mathrm{NaCl}(150 \mathrm{mM})$, a DNA mixture of pLKO-short hairpin control (shCT)/shLOXL2 (7.5 $\mu \mathrm{g}$ ), pCMV-VSVG ( $1.5 \mu \mathrm{~g}$ ), $\mathrm{pMDLg} / \mathrm{pRRE}(4.5 \mu \mathrm{~g})$, and pRSV-Rev $(1.5 \mu \mathrm{~g})$, and polyethylenimine polymer ( $1 \mathrm{mg} / \mathrm{ml}$ ) (Polysciences Inc ), which had been preincubated for 15 min at room temperature. Transfection medium was replaced with fresh medium after 24 h (day 1). The supernatant from the transfection medium at days 2 and 3 was filtered with $0.45 \mu \mathrm{~m}$ filter unit (Merck Millipore) and stored at $4^{\circ} \mathrm{C}$ (both were mixed after day 2). The supernatant mixture was concentrated using Lenti-X Concentrator product (Clontech) and centrifuged at $1500 \times g$ for 45 min at $4^{\circ} \mathrm{C}$. The pellet was resuspended in 1 ml fresh medium, aliquoted ( $100 \mu \mathrm{l})$, and stored at $-20^{\circ} \mathrm{C}$. Aliquots were used to infect MDA-MB-231 cells [6]. For retroviral infections, HEK293 gag-pol cells were used to produce retroviral particles. Cells were transfected as for HEK293T cells with a mixture of $\mathrm{NaCl}(150 \mathrm{mM})$, DNA ( $2.5 \mu \mathrm{~g}$ of pCMV-VSV-G and $7.5 \mu \mathrm{~g}$ of pMSCV, pMSCVLOXL2 wt-FLAG or pMSCV-LOXL2 mutFLAG IRES-GFP vectors) and polyethylenimine polymer ( $1 \mathrm{mg} / \mathrm{ml}$ ) (Polysciences Inc; 23966-1) that had been preincubated for 15 min at room temperature; transfection

Fig. 4 DDR activation is linked to chromatin decondensation in the absence of LOXL2. a Dot graphs indicate the number of foci with $\gamma$ H2AX (left graph) and 53BP1 (right graph) per cell from control and LOXL2 KD cells treated with DMSO or the ATM inhibitor KU55933. b KAP-1 phosphorylation in control or LOXL2 KD cells was analyzed by western blot. Tubulin and total KAP-1 were used as loading controls. As a positive control, MDA-MB-231 cells treated with $0.1 \mu \mathrm{M}$ doxorubicin for 8 h (to generate DSBs) were used. Intervening lanes were removed as indicated (left panel). Chk1 and Chk2 phosphorylation in control and LOXL2 KD cells were analyzed by western blot. Chk1 phosphorylation was detected using the anti-P(S317) Chk1 antibody. For phosphorylated Chk2, a shift was detected using an antitotal Chk2 antibody. GADPH was used as a loading control. All samples were obtained under the same experimental conditions; in addition, positive control samples (irradiated fibroblasts) were run on the same gel as their corresponding control and LOXL2 KD samples. Intervening lanes in the Chk1/2 and GADPH blots were removed as
medium was replaced with fresh medium at 24 and 48 h and processed as explained above. Viral particles were concentrated using Retro-X Concentrator product (Clontech; 631456) and then used to infect MDA-MB-231 cells. HEK293T cells were used to produce lentiviral particles for

indicated (right panel). c Cell cycle profile of control and LOXL2 KD cells at $0,2.5,5$, or 7.5 h after release from a double-thymidine block. Cells were analyzed by fluorescence activated cell sorting (FACS) after propidium iodide staining. d H3S10 phosphorylation levels in control and LOXL2 KD MDA-MB-231 cells were analyzed by western blot. Tubulin was used as a loading control. e Upper panel, MTT assay in control and LOXL2 KD MDA-MB-231 cells; lower panel, colonysurvival assay in control and LOXL2 KD MDA-MB-231 cells. $\gamma$ H2AX staining and foci quantification are shown by immunofluorescence with the indicated antibody after H1 (f) or SUV-39H1 reinfection (g). MDA-MB-231 cells were infected with control or LOXL 2 KD lentivirus, selected with puromycin, and reinfected with GFP (MOCK ${ }^{\mathrm{GFP}+}$ ), histone 1-GFP ( $\mathrm{H} 1^{\mathrm{GFP}+}$ ) (f) or SUV-39H1-GFP (SUV-39 ${ }^{\mathrm{GFP}+}$ ) (g). Cells were fixed after 24 h . Dot graphs indicate the number of $\gamma$-H2AX foci per GFP-positive cell in each condition. Error bars indicate the SD from at least three independent experiments. $* * P$ $<0.01, * * * P<0.001, * * * * P<0.0001$
histone $\mathrm{H} 1(\mathrm{H} 1)-\mathrm{GFP}$ expression. Cells were first grown to $70 \%$ confluency and transfected with a mixture of NaCl ( 150 mM ), a DNA mixture of FUGW-H1-empty vector/ FUGW-H1-GFP $(7.5 \mu \mathrm{~g})$, pCMV-VSVG $(1.5 \mu \mathrm{~g})$, pMDLg/ pRRE $(4.5 \mu \mathrm{~g})$, and pRSV-Rev $(1.5 \mu \mathrm{~g})$, and

polyethylenimine polymer ( $1 \mathrm{mg} / \mathrm{ml}$ ) (Polysciences Inc; 23966-1), which had been preincubated for 15 min at room temperature and processed as explained above. Viral particles were concentrated using Lenti-X Concentrator product (Clontech; 631232) and used to infect MDA-MB-231 cells. For SUV-39H1-GFP rescue experiments, MDA-MB-231 cells infected with either shCT or shLOXL2 were selected for 48 h with puromycin (Puro) $(2.5 \mu \mathrm{~g} / \mathrm{ml})$. After selection, cells were seeded for 24 h and transfected with CGA-pCAGGS-SUV39H1-EGFP-IRES-Puro vector $(2.5 \mu \mathrm{~g})$ using TransIT-X2 Dynamic Delivery System (Mirus Bio LLC; MIR600Q).

## Antibodies and other reagents

The following antibodies were used: anti-FLAG (F7425, Sigma), anti-LOXL2 (NP1-32954, Novus), anti-H3K4me3 (07-473, EMD Millipore), anti-H3K9me3 (07-442, Millipore), anti-phospho-histone H2AX (S139) clone JBW301 (05-636, EMD Millipore), anti-GFP (ab6556, Abcam), anti-53BP1 (NB100-904, Novus Biol.), anti-phosphoCHK1 (S317) (A300-163A, Bethyl), anti-CHK2 clone 7 (05-649, EMD Millipore), anti-cleaved caspase 3 (Asp175) (9661, Cell Signaling), anti-KAP-1 (ab10484, Abcam), anti-Phospho-KAP-1 (S824) (A300-767A, Bethyl), antitubulin (T9026, Sigma), anti-phospho-H3 (S10) (06-570, Millipore), and anti-histone H3 (ab1791, Abcam). The following chemical reagents were used: doxorubicin hydrochloride (Sigma; D1515), cordycepin (Sigma; C3394), and the ATM inhibitor KU55933 (Sigma; SML1109). An anti-H3K4ox antibody was generated from
a synthetic peptide in which fluorenylmethoxycarbonyl protecting group (Fmoc)-6-hydroxynorleucine (BAA1117, Iris Biotech) rather than Fmoc-lysine(Boc) was incorporated at position 4. The peptide was purified ( $>95 \%$ ) by reversedphase high-performance liquid chromatography and its identity was confirmed by mass spectrometry, after which it was coupled to keyhole limpet hemocyanin (KLH) for antibody production. Antibody information can be found in the Supplementary Table 1.

## Cell extracts, histone isolation, and PDX extraction

To obtain nuclear fractions of LOXL2-Flag-transfected MCF-7 cells and HEK293T cells, cells were first lysed in soft-lysis buffer ( 50 mM Tris, 2 mM EDTA, $0.1 \%$ NP-40, and $10 \%$ glycerol, supplemented with protease and phosphatase inhibitors) for 5 min on ice. Samples were centrifuged at $900 \times g$ for 15 min , and the supernatant was discarded. The nuclear pellet was lysed in high-salt lysis buffer $(20 \mathrm{mM}$ HEPES $\mathrm{pH} 7.4,350 \mathrm{mM} \mathrm{NaCl}, 1 \mathrm{mM}$ $\mathrm{MgCl}_{2}, 0.5 \%$ Triton $\mathrm{X}-100$, and $10 \%$ glycerol, supplemented with protease and phosphatase inhibitors) for 30 min at $4{ }^{\circ} \mathrm{C}$, and samples were centrifuged at $16,000 \times g$ for 10 min supernatant NaCl concentration was reduced to 300 mM NaCl by adding balance buffer $(20 \mathrm{mM}$ HEPES pH $7.4,1 \mathrm{mM} \mathrm{MgCl} 2$, and 10 mM KCl . Cells extracts from the different breast cancer cell lines were obtained with SDS lysis buffer ( $2 \%$ SDS, 50 mM Tris- HCl , and $10 \%$ glycerol). Histones were isolated from the different breast cancer cell lines using acid precipitation. For this, cell monolayers were first scraped in 1 ml of lysis buffer $(10 \mathrm{mM}$ Tris pH 6.5 ,

Table 3 Genes downregulated in LOXL2 knockdown

50 mM sodium bisulfite, $10 \mathrm{mM} \mathrm{MgCl} 2,1 \%$ Triton X-100, $8.6 \%$ sucrose, and 10 mM sodium butyrate). Working at $4^{\circ} \mathrm{C}$, pellets were then purified by three rounds of centrifugation $(16,000 \times g$ for 15 s$)$ and resuspension by vortexing, in lysis buffer for the first two rounds and washing buffer ( 10 mM Tris $\mathrm{pH} 7.4,13 \mathrm{mM}$ EDTA) for the final round; supernatant fractions were discarded. The obtained pellets containing chromatin were resuspended in 0.4 N sulfuric acid, the mixture was incubated at $4^{\circ} \mathrm{C}$ for 1 h and then centrifuged at $16,000 \times g$ for 10 min , and the histone-
containing supernatants were kept. Samples were incubated with acetone (1:9) to block the acid overnight at $-20^{\circ} \mathrm{C}$ and then centrifuged at $16,000 \times g$ for 10 min histone pellets were air dried for 5 min and then resuspended in water for analysis. Cell extracts of PDX samples were obtained by disrupting tissue using a pellet pestle (Sigma; Z359947) with lysis buffer ( 50 mM Tris- $\mathrm{HCl} \mathrm{pH} 8,10 \mathrm{mM}$ EDTA, $1 \%$ SDS, and 1 mM DTT). Proteins were separated by SDSpolyacrylamide gel electrophoresis gel and analyzed with the indicated antibodies.

Fig. 5 LOXL2 suppresses sensitivity in TNBC cells. a Cell viability was measured at different timepoints using an MTT assay of cultured different breast cancer cells and PDXs. The effects of doxorubicin, TSA, and doxorubicin plus TSA were analyzed. b Dissociated cells from PDX-549 were orthotopically implanted into NOD/SCID mice and injected intraperitoneally twice weekly with TSA $(0.25 \mathrm{mg} / \mathrm{kg})$, doxorubicin ( $2 \mathrm{mg} / \mathrm{kg}$ mouse weight), or doxorubicin plus TSA. Tumor volumes were measured twice a week and are given as averages. Results are given as averages of six independent tumors $\pm$ SEM

## Recombinant LOXL2 purification

LOXL2-encoding baculovirus were amplified, and LOXL2Flag recombinant proteins (wt and mutant) were produced in Sf9 cells according to standard procedures [3]. Cell lysis was performed as previously described [54]. Cell extracts were incubated with Flag M2 beads for 4 h at $4^{\circ} \mathrm{C}$ and then washed $4 \times$ times with 20 mM HEPES $\mathrm{pH} 7.4,1 \mathrm{mM}$ $\mathrm{MgCl}_{2}, 300 \mathrm{mM} \mathrm{NaCl}, 10 \mathrm{mM} \mathrm{KCl}, 10 \%$ glycerol, and $0.2 \%$ Triton X-100. Recombinant proteins were eluted with the Flag peptide $(1 \mu \mathrm{~g} / \mu \mathrm{l})$ for 1 h at $4^{\circ} \mathrm{C}$.

## Oxidation reaction

Nucleosomes ( $2 \mu \mathrm{~g}$ ) were incubated with recombinant LOXL2 purified protein in oxidation buffer, 20 mM HEPES $\mathrm{pH} 7.4,100 \mathrm{mM} \mathrm{NaCl}, 1 \mathrm{mM} \mathrm{MgCl}$, and 1 mM DTT . Reactions were carried out for the indicated times at $37{ }^{\circ} \mathrm{C}$ and then analyzed by SDS/PAGE and western blotting. To detect the aldehyde group, biotin hydrazide (BTH) ( 5 mM ) was added after the oxidation reaction for 2 h at $25^{\circ} \mathrm{C}$. Finally, biotinylated histones were immunoprecipitated with streptavidin beads, and oxidized H3 was detected by western blot.

## Dot blot assay

For dot blot assays, $1 \mu \mathrm{~g}$ of each peptide (in $10 \mu \mathrm{l}$ of sample) was applied under low vacuum to a prewetted nitrocellulose membrane (Amersham Protran 0.45 nitrocellulose, GE Healthcare) using a dot blot apparatus (HYBRI-DOT Manifold; Life Technologies). After blocking the entire blot in 15 mL of $5 \%$ nonfat dry milk and $0.1 \%$ Tween-20 Trisbuffered saline for 1 h at room temperature, the blot was probed with the indicated antibodies.

## ChIP experiments

For ChIP experiments, cells were first crosslinked in $1 \%$ formaldehyde for 10 min at $37^{\circ} \mathrm{C}$. Crosslinking was stopped by adding glycine to a final concentration of 0.125 M for 2 min at room temperature. Cell monolayers were scraped in cold soft-lysis buffer $(50 \mathrm{mM}$ Tris pH 8.0 , 10 mM EDTA, $0.1 \% \mathrm{NP}-40$, and $10 \%$ glycerol), and incubated 20 min on ice. Nuclei pellets were lysed with SDS lysis buffer ( $1 \%$ SDS, 10 mM EDTA, 50 mM Tris pH 8.0), and extracts were sonicated to generate $200-1500-\mathrm{bp}$ DNA fragments. For immunoprecipitation, supernatants were diluted $1: 10$ with dilution buffer, and samples were
incubated with rotation overnight at $4{ }^{\circ} \mathrm{C}$ with primary antibody or irrelevant immunoglobulin G. Samples were then treated with elution buffer $\left(100 \mathrm{mM} \mathrm{Na} \mathrm{CO}_{3}\right.$ and $1 \%$ SDS) for 1 h at $37^{\circ} \mathrm{C}$ and incubated at $65^{\circ} \mathrm{C}$ overnight after addition of NaCl to a final concentration of 200 mM , to reverse formaldehyde crosslinking. After proteinase K treatment for 1 h at $55^{\circ} \mathrm{C}$, DNA was purified with MinElute PCR purification kit (Qiagen; 28006) and eluted in Milli-Q water. Genomic regions (GRs) were detected by quantitative staining with PCR SYBR Green (Quantabio; 95073), and the ChIP results were quantified relative to the input amount and the amount of H3 immunoprecipitated in each condition.

Peaks of H3K4ox were called from sequence reads detected through ChIP-seq using the MACS2 tool [26]. The chromatin state files for HepG2 and HMEC cells were computed by the ENCODE project using the ChromHMM tool [27] from https://genome.ucsc.edu/cgi-bin/hgFileUi? $\mathrm{db}=\mathrm{hg} 19 \& \mathrm{~g}=\mathrm{wgEncodeBroadHmm}$. Statistical overrepresentation of H3K4ox peaks detected by ChIP-seq was assessed from the two cell lines across several chromatin states: heterochromatin, repressed, insulator, strong enhancer (sum of states 4 and 5), poised/weak enhancer (sum of states 6 and 7), promoter (sum of states 1 and 2), and poised promoter. The contingency table of the Fisher's test carried out for this contained the number of nucleotides within peaks, chromatin states, intersections thereof, and the remaining portion of the genome (computed as the difference from the effective genome size for ChIP-seq peaks calling). The same procedure was applied to detect H3K4ox peak overrepresentation in lamin-associated domains of chromatin, obtained from [55]. ChIP-PCR used the following GR number and peak positions: GR\#1: chr 14 (79003315-79007307); GR\#2: chr 5 (151967551-151971 984); GR\#3: chr 1 (230657019-230658589); GR\#4: chr 2 (41741709-41745780); GR\#5: chr 17 (53951879-5395 5135); GR\#6: chr 4 (62611008-62615505); GR\#7: chr 6 (67550237-67554488); GR\#8: chr 5 (66894215-668990 21); and GR\#9: chr 13 (89334968-89336774). The sequences of the primers used can be found in Supplementary Table 2.

## ATAC-seq and ATAC-qPCR experiments

ATAC experiments were performed as described previously [28]. Cells were harvested and treated with transposase Tn5 (Nextera DNA Library Preparation Kit, Illumina; FC-121-1030). DNA was purified using MinElute PCR purification kit (Qiagen), samples were amplified by PCR using NEBNext High-Fidelity $2 \times$ PCR Master Mix (New England Biolabs; M5041), and DNA was again purified with the MinElute PCR purification kit. Reads produced by ATAC sequencing of two control
(Control) replicates and two LOXL2 KD sequencing replicates (LOXL2 KD) were aligned to the hg19 build of the reference human genome using Bowtie 2 [56] with default parameters for pair-end sequencing. ATAC peaks were then called by combining aligned reads of both replicates of the control and the KD using MACS2. To allow for false discovery rate (FDR) threshold selection further downstream in the analysis, no FDR restrictions were imposed on the ATAC peak calling. For ATACqPCR experiments, the final elution product of the ATAC protocol was diluted 1:50. Incorporation of the transposase Tn5 to GRs was detected by quantitative staining with PCR SYBR Green (Quantabio; 95073). ATACqPCR results for the selected GRs were normalized to the same unaffected GR (HPRT promoter) for each condition. The sequences of the primers used can be found in Supplementary Table 2.

## RNA-seq analysis

Reads produced by RNA-seq of the same replicates as described above of two controls (Control) and two LOXL2 KDs were aligned to the hg 19 build of the reference human transcriptome using TopHat2 [57] with default parameters for pair-end sequencing. Aligned reads were then analyzed using a standard Cufflinks pipeline [58] to detect differentially expressed genes between the two conditions (LOXL2 KD and Control).

## Differential expression analysis of transposable elements (TEs)

The trimmed RNA-seq reads from the two controls and the two LOXL2 samples were processed with the TEtools program [59] using the hg19 annotation of TEs. The obtained count table was then processed with NOIseq [60] to perform a differential expression analysis of LOXL2 against the control. Expression was normalized using the TMM method, whereby TEs with a probability higher than 0.95 of being differentially expressed were considered as statistically significant.

## Replicate correlation

The read count (coverage) at each position of the hg 19 human reference genome was computed for each replicate of the H3K4ox ChIP-seq and the control and LOXL2 KD ATAC sequencing, using the BEDtools genomecov capability [61]. Genomic positions with zero-read counts were filtered out. Replicate files of each experiment were merged to produce a single file aligned by genomic position, and the corresponding Pearson's correlation coefficient of read counts was computed. For the graphical representation of
the correlation, 100,000 genomic positions were randomly selected.

## Analysis of ATAC peaks that overlap with H3K4ox peaks

All significant $\left(P<10^{-5}\right)$ ATAC peaks (LOXL2 KD versus control) and H3K4ox peaks were first intersected with the BEDtools intersect program [61]. Based on this intersection, ATAC peaks were classified as overlapping (if they intersected an H3K4ox peak) or orphan (if not). Only intersections involving more than $95 \%$ of the sequence of ATAC peaks were considered. Control and LOXL2 KD read counts over all genomic positions (see above) were intersected with both overlapping and orphan peaks. Read counts over genomic positions of control and experiment replicates were averaged. To carry out the heatmap representation, peak sequences (overlapping or orphan) were aligned by their summits. For linear representation, the average experimental read counts at each downstream and upstream position were summed for both the experimental and the control counts. Position-wise sums were then divided by the read count sum value obtained for the summit of control read counts, thus making all sums relative to the maximum control value.

## Integrated analysis of H3K40x and ATAC peaks, and differentially expressed genes

The differentially expressed genes detected through the RNA-seq analysis of control and LOXL2 KD cells were selected if they were in close vicinity (either up- or downstream) to overlapping ATAC peaks. Two different distance thresholds ( 0.5 and 1 Mb ) were used to detect close differentially expressed genes.

## Inhibition of RNA synthesis, ATM kinase, and cell cycle analysis

MDA-MB-231-infected cells selected for 48 h with puromycin $(2.5 \mu \mathrm{~g} / \mathrm{ml})$ were seeded and then maintained under puromycin selection.

For inhibition of RNA synthesis, cells were treated at 48 h with $200 \mu \mathrm{M}$ cordycepin (Sigma; C3394) and fixed with $100 \%$ cold ethanol at designated timepoints.

For inhibition of the ATM kinase, cells were incubated at the 24-h timepoint with KU55933 (Sigma; SML1109) for a further 24 h at two different concentrations (either 5 or $10 \mu \mathrm{M})$, or for 2 h with doxorubicin $(1 \mu \mathrm{M})$ as a positive control.

For cell cycle analysis, cells at 48 h after puromycin selection were first synchronized through the double thymidine block protocol. Specifically, cells were seeded to
$50 \%$ confluency, incubated for 14 h with complete growth medium (supplemented with 2 mM thymidine), washed $2 \times$ with phosphate-buffered saline (PBS), and released by a $9-h$ incubation with complete medium growth. Cells were washed again $2 x$ with PBS, incubated $14-\mathrm{h}$ with $2-\mathrm{mM}$ thymidine, and released with complete growth medium. Cells were then harvested at the designated timepoints and fixed with $100 \%$ cold ethanol. After two days, fixed cells were stained with propidium iodide (PI) and analyzed by flow cytometry using BD FACSCalibur (Becton Dickinson). Results were analyzed using BD CellQuest Pro software.

## Non-replicative cell experiment

MDA-MB-231 cells were seeded in coverslips and maintained during all the experiment in Dulbecco's modified Eagle's medium (Biowest; L0106-500) with $0.5 \%$ fetal bovine serum (Gibco; 10270106) at $37{ }^{\circ} \mathrm{C}$ in $5 \% \mathrm{CO}_{2}$. After 24 h , cells were infected with lentiviral particles for LOXL2 KD. After 96 h under selection, cells were fixed with paraformaldehyde $4 \%$ with PBS.

## Comet assay

MDA-MB-231-infected cells under puromycin selection (see above) were seeded at the 48-h timepoint and grown another 48 h more (still with puromycin at $2.5 \mu \mathrm{~g} / \mathrm{ml}$ ). DNA strand breaks were measured at the single-cell level for MDA-MB-231 control or LOXL2 KD cells using an alkaline comet assay with the CometAssay kit (Trevigen, Gaithersburg, MD) following the manufacturer's instructions. Briefly, 5000 cells in $50 \mu$ l PBS were combined with $500 \mu \mathrm{l}$ molten LMAgarose (at $37^{\circ} \mathrm{C}$ ), and $50 \mu \mathrm{l}$ of this was immediately transferred to a CometSlide. After a 10 -min incubation at $4^{\circ} \mathrm{C}$, slides were immersed in $4^{\circ} \mathrm{C}$ lysis solution and incubated overnight at $4^{\circ} \mathrm{C}$. Slides were then immersed in freshly prepared alkaline solution ( 200 mM $\mathrm{NaOH}, 1 \mathrm{mM}$ EDTA $\mathrm{pH}>13$ ) for 1 h at $4^{\circ} \mathrm{C}$ in the dark. For electrophoresis, slides were placed in an electrophoresis slide tray containing alkaline solution and incubated with voltage ( 21 V ) for 30 min . After that, slides were immersed twice in $\mathrm{H}_{2} \mathrm{O}$ for 5 min and then once in $70 \%$ ethanol for 5 min . Samples were dried at $37^{\circ} \mathrm{C}$ and stained with SYBR Green staining solution (SYBR Green I, Invitrogen) using a 1:10000 dilution in TE ( 10 mM Tris- $\mathrm{HCl} \mathrm{pH} 7.5,1 \mathrm{mM}$ EDTA) for 30 min Finally, slides were dried at $37^{\circ} \mathrm{C}$, and cells were imaged using an Olympus BX61 microscope.

## Rescue experiments

MDA-MB-231-infected cells under puromycin selection (see above) were seeded at the 48-h timepoint, incubated
under puromycin selection for an addition 24 h , and then transfected with the SUV-39H1-EGFP vector or reinfected with retroviral particles for LOXL2-FLAG or lentiviral particles for H1 expression. After 24 h, cells were fixed for immunofluorescence.

## Immunofluorescence, image acquisition, and analysis

Cells were fixed with $4 \%$ paraformaldehid for 15 min at room temperature, blocked for 1 h with $1 \%$ PBS-bovine serum albumin, incubated at room temperature for 2 h with primary antibody, washed $3 \times$ with PBS, and then incubated for 1 h at room temperature with the secondary antibody. Cells were washed again $3 \times$ with PBS, incubated for 5 min with $4^{\prime}, 6-$ diamidino-2-phenylindole (DAPI) $(0.25 \mathrm{mg} / \mathrm{ml})$ for cell nuclei staining, and then mounted with fluoromount. Fluorescence images corresponding to DAPI, GFP, $\gamma$-H2AX and 53BP1 were acquired in a Leica TCS SPE microscope using a Leica DFC300 FX camera and the Leica IM50 software.

## Metaphase spreads

For metaphase spread preparations, cells were treated with colcemid $(0.1 \mathrm{ug} / \mathrm{ml})$ for 4 h . Cells were trypsinized, hypotonically swollen in 0.075 M KCl for 15 min at $37^{\circ} \mathrm{C}$, and then fixed $(75 \% \mathrm{MeOH}$ and $25 \%$ acetic acid, ice cold). Metaphase preparations were spread on glass slides, stained with $10 \%$ Giemsa stain (Sigma), and mounted in DPX mounting medium (PanReac). Images were taken using a Leica DM6000 microscope (Leica, Wetzlar, Germany) and analyzed using Fiji Software (https://fiji.sc/).

## Cellular viability experiment

Breast cancer cell lines and PDX cells were seeded in 96-well plates. Cellular viability was analyzed using Thiazolyl Blue Tetrazolium Bromide (MTT) (Sigma; M5655) at different timepoints. The concentrations used were: $0.1 \mu \mathrm{M}$ doxorubicin for all samples; 250-nM TSA for the breast cancer cell lines; and 500-nM TSA for the PDXs cells. Absorbance was detected at 565 nm on Infinite ${ }^{\circledR} 200$ PRO Series Multimode Reader (Tecan Group Ltd.) and analyzed with i-control ${ }^{\mathrm{TM}}$ Microplate Reader Software (Tecan Group Ltd.)

## Cancer PDXs and treatments

Samples from patients with breast cancer were obtained from the operating room and transferred to the pathology department, where breast cancer samples were collected, transferred to the animal facility, and implanted into mice, to generate PDXs. All samples were implanted within 60 to 90 min after surgical removal. All patients willingly signed
an informed consent, and the study was approved by the Ethics Committee of the Vall d'Hebron Hospital.

For in vivo experiments, a tumor from an established PDX was dissociated into single cells by enzymatic digestion (collagenase at $300 \mathrm{U} / \mathrm{ml}$ and hyaluronidase at $200 \mathrm{U} /$ ml ) during 1 h at $37^{\circ} \mathrm{C}$ on a rotating wheel. The solution of digested tumor was treated with $0.025 \%$ trypsin and filtered sequentially using 100 and $40 \mu \mathrm{~m}$ strainers. Isolated cells were plated in culture dishes with DMEM-F12 supplemented with FBS, glutamine, and penicillin/streptomycin. Once the culture was established, $10^{6}$ cells were injected into the number four fat pad of 6-week old NOD. CB17PrkdcSCID/J (NOD/SCID) female mice (Charles River) with Matrigel. For this, mice were anesthetized and shaved, the fourth and fifth sets of nipples were localized, and an inverted Y incision was made from the midline point between the fourth set of nipples, ending between the fourth and fifth sets to expose the fourth and fifth fat pads on one side. After the injection, animals were sutured, and analgesics injected. Animals were kept in a clean cage with drinking water supplemented with $1 \mu \mathrm{M} \quad 17-\beta$-estradiol. Tumor xenografts were measured with callipers every 3 days, and tumor volume was determined using the formula: (length $\times$ width $\left.^{2}\right) \times(\mathrm{pi} / 6)$. At the end of the experiment, animals were anesthetized with a $1.5 \%$ isoflorane-air mixture and were killed by cervical dislocation.

Treatments were administered intraperitoneally twice weekly. One week after cell injection, mice were randomized and treated with TSA $(0.25 \mathrm{mg} / \mathrm{kg})$, doxorubicin ( $2 \mathrm{mg} / \mathrm{kg}$ mouse weight), or doxorubicin plus TSA. The control group was injected with sterile PBS.

Mice were maintained and treated in accordance with institutional guidelines of Vall d'Hebron University Hospital Care and Use Committee.

## Data availability

## GSE96064.

Acknowledgements We would like to thank R. Peña and J. Valle for technical assistance, V.A. Raker for manuscript editing, G. Gil for manuscript reading and advice, A. Jordan for H1-GFP constructs, T. Jenuwein for SUV-39 constructs, and H. Galvez-Garcia for ATAC protocol implementation.
