

Supplemental Materials

Main Inclusion Criteria

Patients aged 18–65 years (inclusive) had a well-documented history of focal epilepsy, compatible with electroencephalogram and clinical history. Patients had focal seizures as defined in the protocol (focal motor seizures without impairment of consciousness or awareness, focal seizures with impairment of consciousness or awareness, and focal seizures evolving to bilateral convulsive seizures), despite prior treatment with at least 2 AEDs (whether as monotherapies or in combination) and concomitant treatment with 1–3 AEDs. Patients had a history of at least 1 focal seizure per week in the 28 days preceding screening and experienced at least 1 focal seizure per week during the 28 days of the baseline period. All medications or interventions for epilepsy were stable for 4 weeks prior to the trial and were maintained throughout the trial. Patients who experienced seizures that were not of a focal onset, or only experienced focal seizures without impaired consciousness or awareness, and without an observable motor component, were not eligible for Part B of the trial.
